Mental Health of the Students and Remote Learning

Satish Kumar*

Dean at School of Education, Languages, Social sciences and Physical education, RIMT University, Punjab, India

ABSTRACT

Abstract: Sustainable development means that the financial improvement that is directed without the consumption of regular asset. The fame of the idea of manageable advancement has expanded colossally in the present speedy business climate. The public's consciousness of different maintainability challenges all over the planet has additionally expanded, and furthermore the vast majority are knowledgeable in them. The mix of the idea of sustainable advancement in administration instruction will help in the production of a manageable culture in our general public, empowering each person to begin acting mindfully and add to positive social change. Psychological well-being as a condition of fruitful exhibition for the duration of the existence course demonstrating physical, intellectual and socioemotional capacities that bring about gainful exercises esteemed critical by one's social network, satisfying social connections and the capacity to rise above moderate psychosocial and ecological issues. The COVID-19 pandemic has constrained numerous schools, colleges, and working environments into lockdown, moving figuring out how to remote and online settings. This paper is focused on online community-oriented remote learning, yet recognizes that different types of remote learning are rehearsed and furthermore talked about the impact of remote learning on the mental health of the students. By improving the mental health of the students, we can increase the pace of sustainable development.

KEYWORDS: Mental health, Students, Remote learning, Sustainability, Psychology

INTRODUCTION

The word mental health is usually used to describe either a level of cognitive or emotional well-being or absence of mental disorder. "A state of well-being in which the individual realizes his or her own abilities, can cope with the normal stresses of life, can work productively and fruitfully, and is also able to make contribution to his or her community" is how the World Health Organization (2005) described mental health. Various viewpoints have also been used to explain mental health. According to psychoanalytic point of view, mental health is a self-possessed property of individuals and a function of intra-psyche development and dynamics are still dominant. It maintains that a person acquires good mental health as a consequence of future early socialization; Psychoanalysis and various other forms of psychotherapy have corrective for unfortunate early development. The mental health is a very wide and relatively ambiguous term and it is difficult to agree on its general application in a single context. Mental health is viewed holistically by psychologists such as Frank (1948) and Fromm (1955), who see it "as a function of the total society, its norms, values, and general style of life." Along with physical, spiritual, and financial well-being, mental health is one of the most significant and interconnected aspects of an individual's life. It is thought that having a healthy mind is essential to achieving life satisfaction (Swami et al., 2007). It also includes a person's ability to enjoy life to attain a balance between life activities and efforts to achieve psychological resilience. A mentally healthy person has all aspects of his well-being, physical, mental, social or super individualistic, well-coordinated into a balanced and

harmonious whole in relationship with the total environment (Kaur, 2015). The capacity to balance one's feelings, goals, objectives, and ideals in day-to-day life is how Bhatia (1982) defined mental health. It refers to the capacity to confront and embrace truth. Pollard and Davidson (2001) defined mental health as a state of successful performance throughout the life course indicating physical, cognitive and socioemotional functions that result in productive activities deemed significant by one's cultural community, fulfilling social relationships and the ability to transcend moderate psychosocial and environmental problems. According to Smail (2006), "Advocates of policy based on subjective/psychological indicators cannot address adequately the problem that people's valuations of their circumstances are crucially conditioned by their frames of reference".

Characteristics of Mentally Healthy Persons

A person with good mental health is found to show the following characteristics:

1. A healthy person always possesses a sense of contentment and well-being. He has the ability to enjoy life and have fun. A mentally healthy person always has a zest of living to laugh and enjoy alone with others.
2. He is capable to deal with stresses of life and has the ability to fight back even in adverse conditions.
3. With the help of positive relationships and meaningful activities, a mentally healthy person participates in experiences of life to complete extent.

4. He has the ability to grow, change and experience different circumstances of life. He must be flexible in order to deal with the deals of life.

5. He has the ability to strike balance between different aspects of life. He must be social as well as remain in solitude with his loved ones. He must have the ability to work and play simultaneously.

6. There should be intellectual development of one's health, spirit, mind and

soul. A sense of well-roundedness and creativity is considered must.

7. A person who is mentally healthy always shows concerns for others. He has the ability to take care of his own and other closed ones. He must have good self-esteem and self-confidence in order to remain physically and mentally active (Kaur,2015).

Man is living in the age of high technology, information, multi-cultures and multi-values. Such age requires us to take every opportunity to face the challenges of life. The current situation of mental health of college students is unoptimistic. The college students face lots of pressures and many of them have certain psychological problems, which do not favour growth and development of the nation. It is the responsibility of the society as a whole to improve the mental health of the students. Almost 15-20% of the students are meeting criteria for a diagnosis of psychiatric illness. Most of the studies reported higher prevalence in women than men. Undergraduate records from a British university, however, showed that only 2-4% of students developed a psychiatric disorder that led to absence from the course and 1% required admission to hospital for psychiatric disturbance (Anjum, 2015).

Remote learning and mental health

The COVID-19 pandemic has forced many schools, universities, and workplaces into lockdown, shifting learning to remote and online contexts. This paper is focussed on online collaborative remote learning, but acknowledges that other forms of remote learning are practiced. The shift to remote learning presents many challenges, particularly relating to student engagement, motivation, social connectedness, and feedback. For teachers, remote learning reduces their capacity to observe verbal and non-verbal behaviours and interactions of students: social behaviours that provide valuable insight into student understanding, engagement, affect, and motivation. This may reduce a teacher's capacity to identify and support a learner who may be challenged by task and environmental difficulties, and limit opportunities to model regulation or support the co-regulation of student learning. Remote learning may, subsequently, increase parental responsibility to support or co-regulate their children's learning, presenting challenges to ILS parents unfamiliar with the strategies that can support learning regulation. Furthermore, this change in parental responsibility may increase strain on the parent-child relationship, particularly if the parent is supporting more than one child or working from home. For students, the increased independence of managing their remote learning may be challenging. Therefore, it could be speculated that with fewer immediate supports in place, learning challenges may be left unmet, and this may result in a reduced sense of competence. Students may also feel socially

disconnected, isolated from their friends and peers who play an important role in building positive affect, engagement, motivation, and learning regulation. Student motivation is influenced by their sense of autonomy, competence, and belonging; a reduced sense of control of their learning, a lowered sense of achievement and competence, and disconnection from the place and people of learning may negatively impact student motivation. Strategies that can promote these qualities in remote learning may therefore be especially valuable (MacMahon, Leggett, & Carroll, 2020).

According to UNESCO, 890 million students in 114 countries, or half of the world's student body, are impacted by the shutdown of educational institutions due to the epidemic. For some students, online learning has become the norm, but there are many obstacles to overcome. Given the socioeconomic disparity that exists in many countries, not all students have access to this type of education. Over 160 nations imposed national shutdown, affecting more than 87% of the global student population, according to UNESCO's monitoring. Local school closures have been introduced in a number of other nations; if similar closures spread across the country, millions more students would face disruptions in their education. Global universities have been unsure about the duration of the coronavirus outbreak and its potential impact on faculty and student mental health. The psychological effects have caused doubt and worry, which has been a major disruption. Conferences and sporting activities have been rescheduled because to the epidemic, and educational institutions are switching from in-person to online instruction. In order to maintain instructors and pupils well and to prepare for the occurrence of diseases on campus, colleges are being compelled to think about extensive preventative procedures. The effect on exchange programs and international students has also been a concern for educational institutions. In the near future, colleges and universities must keep tackling these and other significant and intricate issues. However, the long-term consequences of the epidemic could pose the true threat. Higher education is particularly susceptible and could not be prepared to face a crisis like this because of years of budget cuts and a failure to provide for students' fundamental requirements. Poor kids will suffer more, according to recent data. Insecurity, dread, a sense of loss, and mood swings are already experienced by up to one-third of four-year college and university students and around half of community college students. Experts caution that even when the outbreak has been successfully contained, the effects of this deadly SARS-CoV-2 will continue to affect higher education throughout the world. Academic institutions in the worst impacted regions risk missing a semester or longer. To help international students feel more at ease, universities must think of various ways to combat the coronavirus. Because there are so many ramifications for classes, projects, seminars, and thesis defences, many graduate students experience anxiety and panic. The present upheaval in education is unprecedented in its worldwide scope and pace (Araújo et al., 2020).

Remote learning and working can be good or bad for people, depending on their personality traits. On one hand, those who scored high on openness to experience felt less worried, depressed or miserable when working remotely. Agreeable people and introverts (who tend to be quiet and reserved) also reported feeling less worried and depressed. On the other hand, I found that neurotic people were at a greater risk of reporting poor mental health. They tend to have bad moods

and are easily frustrated, which can cause feelings of worry and depression when working remotely. But that's not all, those who scored low on conscientiousness, or found it hard to plan things carefully, reported feeling worried and gloomy. In short: the messier and disorganised people are, the more likely they will report mental health problems when working remotely (Ogbonnaya & Chidiebere, 2020).

The infection and its effects on physical health are the main emphasis during a pandemic. Changes in behaviour and mental health are frequently viewed as secondary issues. In order to show how the COVID-19 epidemic affected behaviour and mental health in comparison to earlier academic terms, researchers used longitudinal data from a group of 217 college students. Sedentary time and anxiety and depression symptoms both rose over the Winter 2020 school session. Later investigations looked at the relationship between mental health and increasing COVID-19 news coverage and behaviour (derived from mobile sensing data). People were more sedentary, visited fewer places (based on GPS monitoring), and displayed higher levels of worry and despair in response to more COVID-19-related news. According to these assessments, smartphone sensing revealed behavioural changes that are consistent with people following the national and local governments' "Stay Safe, Stay Home" guidelines. Increased levels of anxiety, sadness, and sedentary behaviour were noted throughout the Winter 2020 academic term, indicating a significant behavioural and mental health impact that goes beyond the real reach of the SARS-CoV-2 infection. Students experience a great deal of stress in the days and weeks preceding and following the final test period. Usually, during this period, individuals report comparatively high levels of anxiety and sadness; however, these levels return to baseline following the break.

The cyclical nature of college students' mental health throughout the course of a normal academic term gives our study a unique control that may otherwise be hard to separate from the periodic spikes and dips in stress and anxiety that occur in March as final exams are administered by institutions across the US. Determining how daily occurrences affect students' mental health and behaviour might be aided by understanding how they behave during normal academic cycles. Rare occurrences like the COVID-19 pandemic offer a special chance to look at how behaviours and mental health differ from the norm. We employed linear and quadratic week of academic term variables to account for the cyclical nature of mental health over the academic term. We then searched for interactions and the major impacts of the most recent term (linked to COVID-19). The COVID-19 epidemic was blamed for the higher levels of anxiety, sadness, and inactive time than would typically be seen during a standard term.

Furthermore, none of these three variables showed a return to baseline during the break, which is very different from our earlier research on the same group during earlier academic terms. Although the overall values stayed high above those seen during normal academic holidays, we did see declines in anxiety and despair that mirrored the usual post-final exam dips, suggesting some resilience in the face of COVID-19. This could also align with the time needed to adapt to the quickly evolving social media, policy, and media ecosystem. Although people tend to be more active during breaks, the COVID-19 epidemic is to blame for the significant rise in sedentary behaviour that we saw. Research indicates that exercise,

especially aerobic exercise, has an effect comparable to that of low-dose antidepressants in lowering self-reported depression symptoms. Increased phone use and sedentary time have been linked to anxiety and sadness, according to another research. All things considered, these results imply that people should try to reduce depression symptoms during stay-at-home orders by increasing physical activity and limiting screen time.

We saw a drop in the number of places visited and a fall in the number of phones unlocks, as well as an increase in sedentary behaviour and phone usage time, as COVID-19 news coverage rose. Initially, there was a somewhat unexpected negative relationship between the number of phones unlocks and COVID-19 news; however, this is probably because longer phone unlocks (i.e., screen time) would typically span many phones unlocks. The reduced number of places visited is in line with the "Stay Home, Stay Safe" policies that many governments have put in place. It also contrasts with early research on social distancing among Dutch college students, where social distancing measures were not in place at the time of the study. Anxiety was shown to have a high inferential relationship with COVID-19 news in the combined sensing and mental health model, but depression was found to have a marginally significant relationship. Again, sleep duration, distance travelled, and unlock count were not significant in the combined model (Huckins et al., 2020).

The results of a study (Yorke, et al., 2025) point to important elements that influenced students' experiences, such as limited access to educational materials, more family duties, financial difficulties, and greater stress because of future uncertainty. Girls were more likely to have worked around the house, which reduced their time for schooling. Our findings highlight the need for focused interventions that address the unique needs of students who are most impacted by crises, with an emphasis on both academic learning and mental health and wellness.

In another research the researcher revealed that, COVID-19 pandemic is likely to both directly cause anxiety to students as they worry about the potential health consequences of its spread, as well as indirectly affect their mental well-being through concerns about family finances, their ability to continue their education, and through social isolation. Our phone surveys measured mental well-being using the 5-item MHI-5 index of Veit and Ware (1983). This asks students to answer on a five-point scale how often in the past month they have been happy, felt calm and peaceful, been very nervous, felt downhearted and blue, and felt so down in the dumps that nothing could cheer them up. Scores range from 5 to 25, where higher scores indicate better mental health. We follow several studies in using a cut-off of 17 as an indicator of major depression. We also use the first question from this scale to code a binary indicator of happiness, which takes value one for students who say they were happy all of the time or most of the time. We see that 16 percent of students have mental health scores that indicate major depression, while 68 percent are happy. There is not a strong wealth difference in depression rates, nor does it vary much with region or internet access. We do see higher levels of depression for females, and for indigenous students. Happiness does have a statistically significant wealth gradient, with students from wealthier households, with internet access, and more educated mothers being more likely to be happy (Asanov, et al., 2020).

The majority of undergraduate students' academic performance and mental health suffered as a result of remote learning during COVID-19 (Nano et al., 2025).

According to the results of another study (Mazrekaj & De Witte, 2024), children's learning was significantly hampered and their mental health declined as a result of the unprecedented scope and duration of school closures during COVID-19. Next, we provide policy suggestions on how to guarantee kids' education and psychological growth in the future. In particular, we suggest avoiding generational labels, implementing evidence-based, personality-tailored mental health and social and emotional learning programs in schools, and giving greater attention to students from marginalized groups who are most in need of intervention.

Conclusion

Most students have both access to far-off learning

advancements, and have been occupied with far off picking up during the COVID-19 school shutdown period. Understudies and educators have end up being versatile, with even most of understudies without web access at home figuring out how to participate in some far-off learning. However, a minority of understudies not occupied with any tutoring, with this being increasingly common among understudies from less fortunate foundations. While there is no information accessible on school participation in ordinary occasions to contrast this with, it raises worries about extending imbalance. In numerous understudies are possibly experiencing melancholy, recommending a requirement for giving psychosocial bolster administrations. At last, a constraint of studies is that we measure time spent on learning exercises, yet not how much learning has occurred. Proceeding to screen these understudies after some time to quantify learning impacts is in this manner required.
